Regarding the authentication and registration process, a high level of user friction was observed. Users perceived protocols such as the photographic capture of their voting ID (INE) and the generation of QR codes as complex, time-consuming, and unnecessary procedures. The general expectation of the voters leaned towards a model of direct and simplified access to the web platform. Furthermore, the initial deployment phase presented significant technical issues, such as failures in ID recognition, restrictions on modifying the assigned district, and vulnerabilities in the QR code generation system, particularly with the email delivery option.

Throughout the day, user dissatisfaction did not stem from the visual design of the interface, but rather from deficiencies in the information architecture. Specifically, the lack of clarity and geographic context in the addresses of the district proposals caused confusion. This lack of precise information was pointed out as a barrier by both citizens and city council staff, highlighting a gap in the communication of the initiatives.

In terms of adoption, there was a widespread reluctance to interact directly with the system. The majority of users delegated the registration and voting process to support staff, who acted as mediators using the computer equipment. This dynamic drastically limited the collection of Human-Computer Interaction (HCI) data in a real-world usage environment. Consequently, it was not feasible to evaluate the effectiveness of automated features, such as Optical Character Recognition (OCR) for reading the INE, given that data entry (CURP, name, and district) was performed entirely manually.

Finally, the operational viability of the project was compromised by external hardware limitations, most notably the instability of the provided tablets, which experienced battery retention issues and sudden shutdowns that interrupted the service workflow.
